TN10 night run, 9 to 10 Oct 2026, 21:25 to 05:35 UTC

Counted by Kaspa Pulse for STP. Private. Nothing public before you say yes. Our count = transactions accepted in blocks, per UTC minute, on two independent nodes. All 490 minutes are confirmed by both nodes. Two minutes were recounted afterwards (00:45 and 04:12) and are corrected in the CSV.

The short version

- Everything you pushed until 01:28 landed. 7,541,103 tx accepted in blocks over the night, 6,607,409 of them in the load window 22:00 to 01:28 (mean 526.9 tx/s).
- Highest minute 00:47 UTC, 1,223 tx/s. That is what arrived, not a network limit. Blocks never filled up, the rate followed your senders step by step.
- The chain never stalled. 493 to 716 blocks per minute all night, 9.92 blocks/s on average, longest gap between blocks 1.13 s.
- Miners-off worked. Your mined blocks are 0 from 22:01 to 22:24, the network kept producing blocks at 9.2 per second without you.
- Your chain count and ours agree. Over the 238 minutes where your count is valid, yours is 1.2 % higher in sum (median per minute 3.5 %).
- At 01:28 locus stopped. From there the chain shows base load only (55 tx/s) until the end.

Step by step, from the chain

Step (your steps.csv)	UTC	Accepted in blocks, tx/s	Blocks per min	Your mined blocks per min
C3 baseline	21:30 to 21:39	59	562	45
2x	21:40 to 21:54	56	560	81
2x miners off	22:05 to 22:19	75	552	0
5x	22:30 to 22:44	207	628	123
10x	22:50 to 23:04	398	614	120
20x	23:10 to 23:24	809	558	108
30x	23:30 to 23:44	963	544	118
max	23:50 to 00:04	75	664	133
B1	00:15 to 00:24	104	620	116
hold, live part	00:25 to 01:27	1,055	585	117
hold, after locus stopped	01:29 to 04:44	55	597	0

The max step shows no senders in your log and base load on the chain. If max was meant to run, it did not. The hold from 00:25 is the highest sustained load of the night.

Block rate under load

In the 87 minutes above 800 tx/s, blocks came at 9.55 per second against 9.93 in quiet minutes. Each block carried 109.6 tx on average in those minutes. Correlation between load and block rate over the night is minus 0.25 (midday run 9 Oct was plus 0.58). A small dip, no stall, and not enough data to call it a limit.

About half of all blocks (49.7 %) carried only the coinbase. The network was far from full.

Two things for you to check

1. From 01:28 your stp_sent jumps from about 48,000 to about 1.05 million per minute, for 196 minutes until 04:44, while the chain shows base load only and your chain count is marked invalid. It looks like the senders kept firing at a dead locus and counted failed submits as sent. Worth a look before anyone reads that column as load.

2. The mining address in the plan produced blocks only from 21:27 to 21:31. Your mined_blocks column shows you mining until 01:28. Can you send us your actual payout address privately? Then we can show your mining share per step from the chain.

Limits of this count

- We count what lands in blocks. What was sent but never accepted is only in your logs.
- The mempool on our nodes and yours disagree after 01:30 (about 2,880 against about 200). We do not use mempool numbers for any conclusion here.
- 05:35 to 06:30 we kept counting, base load only. Not in the CSV.
